## Alert Detail

Alto	Cross Site Scripting (Refletido)
Descrição	<p>Cross-site Scripting (XSS) é uma técnica de ataque que envolve a replicação e execução de código fornecido pelo invasor na instância do navegador do usuário. Uma instância do navegador pode ser um cliente de navegador padrão ou um objeto de navegador incorporado em um produto de software, como o navegador no WinAmp, um leitor de RSS ou um cliente de e-mail. O código em si é geralmente escrito em HTML/JavaScript, mas também pode se estender para VBScript, ActiveX, Java, Flash ou qualquer outra tecnologia compatível com navegador.</p> <p>Quando um invasor faz com que o navegador de um usuário execute seu código, o código será executado dentro do contexto de segurança (ou zona) do site de hospedagem. Com este nível de privilégio, o código tem a capacidade de ler, modificar e transmitir quaisquer dados confidenciais acessíveis pelo navegador. Um usuário afetado por script de cross-site pode ter sua conta sequestrada (roubo de cookie), seu navegador redirecionado para outro local ou possivelmente mostrando conteúdo fraudulento fornecido pelo suposto site que está visitando. Os ataques de script cross-site comprometem essencialmente a relação de confiança entre um usuário e o site. Aplicativos que utilizam instâncias de objeto de navegador que carregam conteúdo do sistema de arquivos podem executar código na zona da máquina local, permitindo o comprometimento do sistema.</p> <p>Existem três tipos de ataques de Cross-site Scripting: não persistente, persistente e baseado em DOM.</p> <p>Ataques não persistentes e ataques baseados em DOM exigem que o usuário visite um link especialmente criado com código malicioso ou visite uma página da web maliciosa contendo um formulário da web que, quando postado no site vulnerável, montará o ataque. O uso de um formulário mal-intencionado geralmente ocorre quando o recurso vulnerável aceita apenas solicitações HTTP POST. Nesse caso, o formulário pode ser enviado automaticamente sem o conhecimento da vítima (por exemplo, usando JavaScript). Ao clicar no link malicioso ou enviar o formulário malicioso, a carga XSS será ecoada de volta e será interpretada pelo navegador do usuário e executada. Outra técnica para enviar solicitações quase arbitrárias (GET e POST) é usar um cliente incorporado, como o Adobe Flash.</p> <p>Ataques persistentes ocorrem quando o código malicioso é enviado a um site onde é armazenado por um período de tempo. Exemplos dos alvos favoritos de um invasor geralmente incluem postagens em quadros de mensagens, mensagens de webmail e software de bate-papo na web. Não é requerido do usuário desavisado, que interaja com qualquer site/link adicional (por exemplo, um site invasor ou um link malicioso enviado por e-mail), basta simplesmente visualizar a página da web que contém o código.</p>

Instances	19
Solution	<p>Fase: Arquitetura e Design.</p> <p>Use uma biblioteca verificada ou framework que não permita que essa vulnerabilidade ocorra, ou forneça construções/implementações que tornem essa vulnerabilidade mais fácil de evitar.</p> <p>Exemplos de bibliotecas e frameworks que facilitam a geração de saída codificada adequadamente incluem a biblioteca Anti-XSS da Microsoft, o módulo de codificação OWASP ESAPI e o Apache Wicket.</p> <p>Fases: Implementação   Arquitetura e Design.</p> <p>Compreenda o contexto no qual seus dados serão usados e a codificação que será esperada. Isso é especialmente importante ao transmitir dados entre componentes diferentes ou ao gerar saídas que podem conter várias codificações ao mesmo tempo, como páginas da web ou mensagens de e-mail com várias partes. Estude todos os protocolos de comunicação e representações de dados esperados para determinar as estratégias de codificação necessárias.</p> <p>Para quaisquer dados que serão enviados para outra página da web, especialmente quaisquer dados recebidos de entradas externas, use a codificação apropriada em todos os caracteres não alfanuméricos.</p> <p>Consulte a Página de Dicas de Prevenção de XSS para obter mais detalhes sobre os tipos de codificação e escape que são necessários.</p> <p>Fase: Arquitetura e Design.</p> <p>Para todas as verificações de segurança realizadas no lado do cliente, certifique-se de que essas verificações sejam duplicadas no lado do servidor, a fim de evitar a CWE-602. Invasores podem ignorar as verificações do lado do cliente, modificando os valores após a realização das verificações ou alterando o cliente para remover as verificações do lado do cliente completamente. Em seguida, esses valores modificados poderiam ser enviados ao servidor.</p> <p>Se disponível, use mecanismos estruturados que impõem automaticamente a separação entre dados e código. Esses mecanismos podem ser capazes de fornecer citação, codificação e validação relevantes automaticamente, em vez de depender do desenvolvedor para fornecer esse recurso em cada ponto onde a saída é gerada.</p> <p>Fase: Implementação.</p>

	<p>Para cada página web gerada, use e especifique uma codificação de caracteres, como ISO-8859-1 ou UTF-8. Quando uma codificação não é especificada, o navegador pode escolher uma codificação diferente, tentando adivinhar por eliminação qual codificação está realmente sendo usada pela página da web. Isso pode fazer com que o navegador da web trate certas sequências como especiais, abrindo o cliente para ataques XSS sutis. Consulte a CWE-116 para obter mais informações sobre mitigações relacionadas à codificação /escape.</p> <p>Para ajudar a mitigar os ataques XSS contra cookie de sessão do usuário, defina o cookie de sessão como HttpOnly. Em navegadores que suportam o recurso HttpOnly (como versões mais recentes do Internet Explorer e Firefox), esse atributo pode impedir que o cookie de sessão do usuário seja acessível a scripts mal-intencionados do lado do cliente que usam document.cookie. Esta não é uma solução completa, já que HttpOnly não é compatível com todos os navegadores. Mais importante ainda, XMLHttpRequest e outras poderosas tecnologias de navegadores fornecem acesso de leitura a cabeçalhos HTTP, incluindo o cabeçalho Set-Cookie no qual o sinalizador HttpOnly é definido.</p> <p>Presuma que toda a entrada de dados é maliciosa. Use uma estratégia de validação de entrada "aceita como boa", ou seja, use uma lista de permissões de entradas aceitáveis que estejam estritamente em conformidade com as especificações. Rejeite quaisquer entradas que não estejam estritamente de acordo com as especificações ou transforme-as em algo que esteja. Não confie exclusivamente na procura de entradas maliciosas ou malformadas (ou seja, não confie em uma lista de negação). No entanto, as listas de negação podem ser úteis para detectar ataques em potencial ou determinar quais entradas estão tão malformadas que devem ser rejeitadas imediatamente.</p> <p>Ao executar a validação de entradas de dados, considere todas as propriedades potencialmente relevantes, incluindo comprimento, tipo de entrada, a gama completa de valores aceitáveis, entradas ausentes ou extras, sintaxe, consistência entre campos relacionados e conformidade com as regras de negócios. Como um exemplo de lógica de regra de negócios, "barco" pode ser sintaticamente válido porque contém apenas caracteres alfanuméricos, mas não é válido se você estiver esperando cores como "vermelho" ou "azul".</p> <p>Certifique-se de realizar a validação de entrada em interfaces bem definidas dentro do aplicativo. Isso ajudará a proteger o aplicativo, mesmo se um componente for reutilizado ou movido para outro lugar.</p>

Instances	11
	Fase: Arquitetura e Design.
	Use uma biblioteca verificada ou framework que não permita que essa vulnerabilidade ocorra, ou forneça construções/implementações que tornem essa vulnerabilidade mais fácil de evitar.
	Exemplos de bibliotecas e frameworks que facilitam a geração de saída codificada adequadamente incluem a biblioteca Anti-XSS da Microsoft, o módulo de codificação OWASP ESAPI e o Apache Wicket.
	Fases: Implementação   Arquitetura e Design.
	Compreenda o contexto no qual seus dados serão usados e a codificação que será esperada. Isso é especialmente importante ao transmitir dados entre componentes diferentes ou ao gerar saídas que podem conter várias codificações ao mesmo tempo, como páginas da web ou mensagens de e-mail com várias partes. Estude todos os protocolos de comunicação e representações de dados esperados para determinar as estratégias de codificação necessárias.

Solution	<p>Para quaisquer dados que serão enviados para outra página da web, especialmente quaisquer dados recebidos de entradas externas, use a codificação apropriada em todos os caracteres não alfanuméricos.</p> <p>Consulte a Página de Dicas de Prevenção de XSS para obter mais detalhes sobre os tipos de codificação e escape que são necessários.</p> <p>Fase: Arquitetura e Design.</p> <p>Para todas as verificações de segurança realizadas no lado do cliente, certifique-se de que essas verificações sejam duplicadas no lado do servidor, a fim de evitar a CWE-602. Invasores podem ignorar as verificações do lado do cliente, modificando os valores após a realização das verificações ou alterando o cliente para remover as verificações do lado do cliente completamente. Em seguida, esses valores modificados poderiam ser enviados ao servidor.</p> <p>Se disponível, use mecanismos estruturados que impõem automaticamente a separação entre dados e código. Esses mecanismos podem ser capazes de fornecer citação, codificação e validação relevantes automaticamente, em vez de depender do desenvolvedor para fornecer esse recurso em cada ponto onde a saída é gerada.</p> <p>Fase: Implementação.</p> <p>Para cada página web gerada, use e especifique uma codificação de caracteres, como ISO-8859-1 ou UTF-8. Quando uma codificação não é especificada, o navegador pode escolher uma codificação diferente, tentando adivinhar por eliminação qual codificação está realmente sendo usada pela página da web. Isso pode fazer com que o navegador da web trate certas sequências como especiais, abrindo o cliente para ataques XSS sutis. Consulte a CWE-116 para obter mais informações sobre mitigações relacionadas à codificação /escape.</p> <p>Para ajudar a mitigar os ataques XSS contra cookie de sessão do usuário, defina o cookie de sessão como HttpOnly. Em navegadores que suportam o recurso HttpOnly (como versões mais recentes do Internet Explorer e Firefox), esse atributo pode impedir que o cookie de sessão do usuário seja acessível a scripts mal-intencionados do lado do cliente que usam document.cookie. Esta não é uma solução completa, já que HttpOnly não é compatível com todos os navegadores. Mais importante ainda, XMLHttpRequest e outras poderosas tecnologias de navegadores fornecem acesso de leitura a cabeçalhos HTTP, incluindo o cabeçalho Set-Cookie no qual o sinalizador HttpOnly é definido.</p> <p>Presuma que toda a entrada de dados é maliciosa. Use uma estratégia de validação de entrada "aceita como boa", ou seja, use uma lista de permissões de entradas aceitáveis que estejam estritamente em conformidade com as especificações. Rejeite quaisquer entradas que não estejam estritamente de acordo com as especificações ou transforme-as em algo que esteja. Não confie exclusivamente na procura de entradas maliciosas ou malformadas (ou seja, não confie em uma lista de negação). No entanto, as listas de negação podem ser úteis para detectar ataques em potencial ou determinar quais entradas estão tão malformadas que devem ser rejeitadas imediatamente.</p> <p>Ao executar a validação de entradas de dados, considere todas as propriedades potencialmente relevantes, incluindo comprimento, tipo de entrada, a gama completa de valores aceitáveis, entradas ausentes ou extras, sintaxe, consistência entre campos relacionados e conformidade com as regras de negócios. Como um exemplo de lógica de regra de negócios, "barco" pode ser sintaticamente válido porque contém apenas caracteres alfanuméricos, mas não é válido se você estiver esperando cores como "vermelho" ou "azul".</p> <p>Certifique-se de realizar a validação de entrada em interfaces bem definidas dentro do aplicativo. Isso ajudará a proteger o aplicativo, mesmo se um componente for reutilizado ou movido para outro lugar.</p>

Médio	<b>Ausência de tokens Anti-CSRF</b>
Descrição	<p>Não foram localizados tokens Anti-CSRF no formulário de submissão HTML.</p> <p>Uma falsificação de solicitação entre sites (Cross-Site Request Forgery ou simplesmente CSRF) é um ataque que envolve forçar a vítima a enviar uma solicitação HTTP a um destino alvo sem seu conhecimento ou intenção, a fim de realizar uma ação como a vítima. A causa implícita é a funcionalidade do aplicativo usando ações previsíveis em URLs /formulários, de maneira repetível. A natureza do ataque é que o CSRF explora a confiança que um site tem em um usuário. Em contrapartida, um ataque do tipo Cross-Site Scripting (XSS) explora a confiança que um usuário tem em um site. Como o XSS, os ataques CSRF não são necessariamente entre sites, mas também podem ser. A falsificação de solicitação entre sites também é conhecida por "CSRF", "XSRF", "one-click attack", "session riding", "confused deputy", e "sea surf".</p> <p>Os ataques CSRF são efetivos em várias situações, incluindo:</p> <ul style="list-style-type: none"> <li>* - A vítima tem uma sessão ativa no site de destino;</li> <li>* - A vítima está autenticada por meio de autenticação HTTP no site de destino;</li> <li>* - A vítima está na mesma rede local do site de destino.</li> </ul>

	O CSRF era usado principalmente para executar ações contra um site-alvo usando os privilégios da vítima, mas técnicas recentes foram descobertas para vazamento de informações obtendo acesso às respostas. O risco de vazamento/divulgação não autorizada de informações aumenta drasticamente quando o site de destino é vulnerável a XSS, porque o XSS pode ser usado como uma plataforma para CSRF, permitindo que o ataque opere dentro dos limites da política de mesma origem.

Médio	Content Security Policy (CSP) Header Not Set
Descrição	Content Security Policy (CSP) is an added layer of security that helps to detect and mitigate certain types of attacks, including Cross Site Scripting (XSS) and data injection attacks. These attacks are used for everything from data theft to site defacement or distribution of malware. CSP provides a set of standard HTTP headers that allow website owners to declare approved sources of content that browsers should be allowed to load on that page — covered types are JavaScript, CSS, HTML frames, fonts, images and embeddable objects such as Java applets, ActiveX, audio and video files.

Solution	<p>Modern Web browsers support the Content-Security-Policy and X-Frame-Options HTTP headers. Ensure one of them is set on all web pages returned by your site/app.</p> <p>If you expect the page to be framed only by pages on your server (e.g. it's part of a FRAMESET) then you'll want to use SAMEORIGIN, otherwise if you never expect the page to be framed, you should use DENY. Alternatively consider implementing Content Security Policy's "frame-ancestors" directive.</p>

<b>Baixo</b>	<b>O servidor vaza informações por meio dos campos de cabeçalho de resposta HTTP "X-Powered-By"</b>
Descrição	O servidor da web/aplicativo está vazando informações por meio de um ou mais cabeçalhos de resposta HTTP "X-Powered-By". O acesso a essas informações pode facilitar que os invasores identifiquem outras estruturas/componentes dos quais seu aplicativo da web depende e as vulnerabilidades às quais esses componentes podem estar sujeitos.

Plugin Id	<a href="#">10036</a>

<b>Baixo</b>	<b>X-Content-Type-Options Header Missing</b>
Descrição	The Anti-MIME-Sniffing header X-Content-Type-Options was not set to 'nosniff'. This allows older versions of Internet Explorer and Chrome to perform MIME-sniffing on the response body, potentially causing the response body to be interpreted and displayed as a content type other than the declared content type. Current (early 2014) and legacy versions of Firefox will use the declared content type (if one is set), rather than performing MIME-sniffing.

Método	GET
Ataque	
Evidence	
Other Info	This issue still applies to error type pages (401, 403, 500, etc.) as those pages are often still affected by injection issues, in which case there is still concern for browsers sniffing pages away from their actual content type. At "High" threshold this scan rule will not alert on client or server error responses.

Instances	82
Solution	Ensure that the application/web server sets the Content-Type header appropriately, and that it sets the X-Content-Type-Options header to 'nosniff' for all web pages.  If possible, ensure that the end user uses a standards-compliant and modern web browser that does not perform MIME-sniffing at all, or that can be directed by the web application /web server to not perform MIME-sniffing.

Informativo	GET for POST
Descrição	A request that was originally observed as a POST was also accepted as a GET. This issue does not represent a security weakness unto itself, however, it may facilitate simplification of other attacks. For example if the original POST is subject to Cross-Site Scripting (XSS), then this finding may indicate that a simplified (GET based) XSS may also be possible.

Informativo	Má Combinação de Charset (Cabeçalho versus Meta Content-Type Charset)
Descrição	<p>This check identifies responses where the HTTP Content-Type header declares a charset different from the charset defined by the body of the HTML or XML. When there's a charset mismatch between the HTTP header and content body Web browsers can be forced into an undesirable content-sniffing mode to determine the content's correct character set.</p> <p>An attacker could manipulate content on the page to be interpreted in an encoding of their choice. For example, if an attacker can control content at the beginning of the page, they could inject script using UTF-7 encoded text and manipulate some browsers into interpreting that text.</p>

Informativo	User Controllable HTML Element Attribute (Potential XSS)
Descrição	This check looks at user-supplied input in query string parameters and POST data to identify where certain HTML attribute values might be controlled. This provides hot-spot detection for XSS (cross-site scripting) that will require further review by a security analyst to determine exploitability.
URL	<a href="http://testphp.vulnweb.com/guestbook.php">http://testphp.vulnweb.com/guestbook.php</a>
Método	POST
Ataque	
Evidence	
Other Info	User-controlled HTML attribute values were found. Try injecting special characters to see if XSS might be possible. The page at the following URL: <a href="http://testphp.vulnweb.com/guestbook.php">http://testphp.vulnweb.com/guestbook.php</a> appears to include user input in: a(n) [input] tag [value] attribute The user input found was: name=anonymous user The user-controlled value was: anonymous user
URL	<a href="http://testphp.vulnweb.com/guestbook.php">http://testphp.vulnweb.com/guestbook.php</a>
Método	POST
